Introduction — What is the risk-sharing DB? —

Simulation Assumptions

Difference of benefits among DB, DC and RS plan

Valuation of the risk covered by sponsors and participants

Three approaches to reduce the risk
Risk-sharing DB (RS) was introduced as an intermediate between the defined-benefit plan (DB) and the defined-contribution pension plan (DC).

Employer and employees share risks.
Key features of the RS plan

- Pre-defined benefits may be exposed to adjustment depending on the plan’s financial status
- Employers additionally contribute more than the normal contributions as a risk margin

### Calculations

\[
\frac{\text{Assets} + \text{PV of contributions}}{\text{PV of benefits}} = 1
\]

\[
\frac{\text{Assets} + \text{PV of contributions} - \text{Risk margin}}{\text{PV of benefits}}
\]
Rules for Risk margin measurement

- There are two calculation methods prescribed by law named: "standard method“, and “special method”
- In the standard method, the following 1 + 2
  ① The risk of asset fluctuations, defined as the risk that may occur once in 20 years
  ② The risk of declining the discount rate, specifically by 1.0%
- In the special method, include other risk occurring from liabilities (e.g., employee turnover and mortality)
Advantages of the RS plan

- No need for sudden additional funding
  → **Planned cash flow**

- Accounted for as DC plans under Japanese GAAP and IFRS
  → **Eliminate or reduce PBO**

- Plan assets are pooled and managed collectively
  → **Better investment performance than the DC plan**
Disadvantages of the RS plan

- Raised Contributions for a certain period after introduction
- Participants/retirees receive benefits that may be adjusted
- The mechanism of the benefit adjustment is not simple

→ This complexity makes it unclear how much risks sponsors and participants/retirees bear respectively
Simulation Assumptions

Introduction — What is the risk-sharing DB? —

Simulation Assumptions

Difference of benefits among DB, DC and RS plan

Valuation of the risk covered by sponsors and participants

Three approaches to reduce the risk
Simulation Assumptions (1/3)

- An age composition of the participants/retirees is time-homogeneous

- The type of formula
  - Cash balance plan
    - Hypothetical account balances = Pay credit + interest credit
    - Interest rate is fixed at 3.0% per year
    - The pension benefit is an annuity certain for 20 years
    - The lump sum death benefit is paid as the hypothetical account balances

- Risk margin
  - Standard method
    - The risk of asset fluctuations = 2.06σ of plan assets
    - The risk occurring from liability = Increase in liabilities due to 1% decrease in discount rate
Simulation Assumptions (2/3)

- Asset mix used in the simulation
  - Constant rebalance strategy
  - One-year return has the normal distribution of $N(3.0\%, 8.26\%)

</tbody>
</table>
Simulation Assumptions (3/3)

- The age composition

- Rates of salary increase

- Mortality rates
Initial status of BS/PL

- Payments in a year are scaled to be just 100 for convenience
- It also means that the total amount of benefits which a certain generation should be paid is 100

**Balance sheet**

<table>
<thead>
<tr>
<th>Risk margin</th>
<th>Estimated risk occurring from liabilities 434</th>
</tr>
</thead>
<tbody>
<tr>

</thead>
<tbody>
<tr>
<td>Investment income 55</td>
<td></td>
</tr>
</tbody>
</table>

(note 1) The contribution is paid at the beginning of each year, while the benefit is received at the end of each year
(note 2) Time-homogeneous age composition are assumed
- Risk-buffer contributions (contributions on top of the normal contributions in order to build up a risk buffer) are zero for the RS plan.
- In this way, it can be considered that all the risks are put on participants/retirees because the additional burden of the employer is zero for the RS plan.
- In RS and DC plan, only the employees are exposed to all risks under this premise.
Distribution of the total amounts of benefits (1/2)

- The fluctuation range in the RS plan spreads more slowly than the DC plan
Distribution of the total amounts of benefits (2/2)

</tbody>
</table>

**Risks covered by participants of generation \( x \)**

\[ RP_x = \sum_{x \in X} \text{Max}(b_{DB} - CVaR_{b_x}(\beta), 0) \]

- **Age \( x \)**
- **Benefits of RS \( b_x \)**
- **Benefits of DB \( b_{DB} \)**
- **\( CVaR_{b_x}(\beta) \)**
- **\( VaR_{b_x}(\beta) \)**
Parameters Setting

- Total amount of benefits paid to a certain generation from a DB plan is $b_{DB} = 100$
- Confidence level of CVaR is $\beta = 0.95$
- The risk covered by retirees is $RP_R = \sum_{x \in R} RP_x$, where $R = \{x | x \geq 60\}$
- The risk covered by active participants is $RP_{pa} = \sum_{x \in Pa} RP_x$, where $Pa = \{x | 18 \leq x \leq 59\}$
- The risk covered future participants for 40 years is $RP_{pf} = \sum_{x \in Pf} RP_x$, where $Pf = \{x | -22 \leq x \leq 17\}$
- The risk-buffer contributions are lump-sum contributions at the start of the simulation.

Risks covered by participants of generation $x$

$$RP_x = \sum_{x \in X} \text{Max}(b_{DB} - CVaR_{bx}(\beta), 0)$$
Risks covered by sponsors and participants/retirees in RS plan

- Increasing the risk covered by the plan sponsor, the participants/retirees’ risk decrease
- Point A, B and C represents the risk-balanced point between them
Three approaches to reduce the risk

Introduction — What is the risk-sharing DB? —

Simulation Assumptions

Difference in benefits among DB, DC and RS plan

Valuation of the risk covered by sponsors and participants
Three approaches to reduce the risk are as follows

- Change the portfolio
  - Measure the effects of adopting the portfolio [B] and [C] in the slide 11 in addition to the portfolio [A]
- Abolish upward adjustment of benefits
- Prolong risk-buffer contributions periods
Effects of changing the portfolio

- Increasing the expected return will reduce the risk of future generations, but will increase the overall risk.
- Who will take the risk for whom?
Effects of abolishing upward adjustment of benefits

- The risk of the participants/retirees is lowered
- However, there is almost no impact where the employer's risk burden is small

![Graph showing the effects of abolishing upward adjustment of benefits.](image)
Effects of prolonging risk-buffer contributions

- It is very effective to prolong risk-buffer contributions periods to reduce risk
- The risk of active and future generations has been significantly reduced
Conclusion

- Quantitative approach with Monte Carlo simulation cleared the difference in the characteristics of the benefits in the DB, DC and RS plan.
- I employed the CVaR as the evaluation measures and evaluated the risk transferred to the employees from employers.
- Prolongation of risk-buffer contributions is very effective to reduce the risk in the RS plan.
